

Image Bioinformatics

Image semantics in life sciences research

Graham Klyne

Image Bioinformatics Research Group of the Oxford e-Science Centre

Department of Zoology

University of Oxford, UK

Introduction

Image Bioinformatics Research Group

- We are: David Shotton, Chris Catton, Graham Klyne, Liz Mellings, based in the Zoology Department at Oxford
- Backgrounds in: cell biology, microscopy, animal behaviour, video, database design, ontology, Internet and Web standards, Semantic Web, data curation
- Part of the Oxford e-Science Centre
- Drawing on expertise and standards in biology, computing and ontologies, applied to life-sciences research

Technical Goals

- Storage technology is **not** a goal for us
- Assembly of systems to capture and publish research images and metadata with associated high-level descriptions
- Preserving the association between raw data and high-level descriptions
- Provide access to data in terms of research domain concepts
- Combine research image data with other online resources (gene databases, literature databases, *etc.*)
- Web-style interoperability and evolveability

Drosophila Testis Gene Expression Database (DTGED) Project

- Research the function of genes whose expression is dependent on specific (*a/y*-class) proteins
 - PIs: Dr Helen White-Cooper and Dr David Shotton
 - We are working closely with the DTGED research team based in the Zoology Department, University of Oxford
- Genes code for the production of complex chemicals (enzymes, proteins, etc) used in biological processes
 - But the *expression* of any gene is dependent on the cell environment, including the presence of other gene products
 - Observable biological consequences (phenotypes) may result from subtle interactions between many gene products and other factors
 - This project aims to document such interactions in *drosophila* (fruit fly) spermatogenesis

Adult *Drosophila* testis

Adult *Drosophila* testis

Images of Expression Patterns

- To an expert observer these images clearly show gene expression at different stages of spermatogenesis
- Each image corresponds to a different combination of gene and a strain of *drosophila*
- These *in situ* hybridization images are the “end game” - the final stage of a non-trivial process of screening and preparation
- Reproducibility and interpretation requires that the preparatory steps are recorded along with the images

DTGED Experimental Data Flows

DTGED Technologies Used

- Minimalist approach to development; working with available web-based tools, etc.
- Protégé+Racer (DL reasoner) for design and testing of ontologies for experimental data
 - Note that expert annotations are open-ended
- BioImage for Ontology-directed capture and staging of annotations and observations
 - Extends original purpose of BioImage
- Open Microscopy Environment (OME) for capture and staging of images and image metadata
- Haskell for “conditioning” Excel spreadsheet data and combining it with other data sources
- BioImage for publication of images and metadata

Experiences with OME

- Our focus:
 - **Manual** annotation of images rather than high-volume automated processing
 - Integrate image annotations with other data used in experimental workflows
- Our experience (as of 3-4 months ago):
 - OME can be a difficult system to get into
 - Complex, monolithic system
 - Documentation seems to assume audience already “on message”
 - Limited and awkward in area of user annotation
 - Steep learning curve for even simple project-specific annotations
 - Problems with export of annotations
 - Data model is not easy to understand (2 forms?)

Desiderata for the Future

- OME/XML is the key component
 - the rest is “mere engineering”
- Clarify what the OME core needs to do
 - move anything that doesn't need to be there
 - minimize the core storage engine that needs to scale
 - provide other functions as “satellite” applications
- Where possible, design for scaling at the edge
 - No need to handle UI functions in the core database
- Make it easy for users to enlarge the system
 - Note: I would not choose to use Perl or Java for project-specific data handling (Python, Haskell, Ruby, or even Excel, are quicker for project-specific applications)
- “Small pieces, loosely coupled” (software *and* data mode)

Making Interoperability Easy

- Well-defined data format and semantics (OME/XML)
- Provide simple interfaces to access/update stored data
 - e.g. simple HTTP GET/POST
- Provide stand-alone tools and libraries to manipulate OME/XML data
- Thoroughly document the interfaces and data formats, including assumptions and limitations
- Plan to interwork with modern lightweight frameworks for Web UI work
 - e.g. Ruby/Rails, Python/Turbogears
 - Ajax for responsive possibilities
- Enable users to add functionality using any tools

Open Microscopy Web ?

- Enable researchers to review and find new results using existing published data - but first it must be published!
- The Web does not have a centre
- OME providing nodes in a web of research image data
- Separate publication from quality/review process
 - Use the web for raw publication
 - Anyone can publish data on the web, regardless of quality
 - Others can review and index data that meets appropriate criteria (technical standards, trust in researchers, peer review, etc.)
- Develop tools to combine disparate research information
 - Syntax translation to common form for exchange
 - Use ontologies and ontological engineering techniques to find correspondences
